

Class Creational

Client

Define an interface for creating an object, but let subclasses decide which class to instantiate. Factory Method lets a class defer instantiation to subclasses.

Also Known As

Virtual Constructor

Motivation

Frameworks use abstract classes to define and maintain relationships between objects. A framework is often responsible for creating these objects as well.

Consider a framework for applications that can present multiple documents to the user. Two key abstractions in this framework are the classes `Application` and `Document`. Both classes are abstract, and clients have to subclass them to realize their application-specific implementations. To create a drawing application, for example, we define the classes `DrawingApplication` and `DrawingDocument`. The `Application` class is responsible for managing `Documents` and will create them as required—when the user selects `Open` or `New` from a menu, for example.

Because the particular `Document` subclass to instantiate is application-specific, the `Application` class can't predict the subclass of `Document` to instantiate—the `Application` class only knows *when* a new document should be created, not *what kind* of `Document` to create. This creates a dilemma: The framework must instantiate classes, but it only knows about abstract classes, which it cannot instantiate.

The Factory Method pattern offers a solution. It encapsulates the knowledge of which `Document` subclass to create and moves this knowledge out of the framework.
